Project No. 88-537 August 1988

Paul C. Rizzo Associates, Inc. CONSULTANTS

Proposal

Assessment of the Presence of TCE and Other Volatile Organic Substances

Beaver, Pennsylvania

Westinghouse Electric Corporation Pittsburgh, Pennsylvania

SET 0029638

WPL 005 5600

August 11, 1988

Ms. Linda LeGoullon Project Engineer Westinghouse Environmental Affairs Remediation Group Westinghouse Electric Corporation Gateway Center Pittsburgh, PA 15222

Professional Consulting Services Assessment of the Presence of TCE and Other Volatile Organic Substances Westinghouse Electric Facility Beaver, Pennsylvania

Dear Ms. LeGoullon:

In response to your recent verbal request, Rizzo Associates proposes to provide professional consulting services to Westinghouse for assessing the nature and extent of TCE and other volatile organic substances in the soil and groundwater at the Westinghouse Electric Corporation Facility in Beaver, Pennsylvania and to assess the relationship, if any, between the Westinghouse plant and current conditions at the well field of the Vanport Municipal Water Authority.

Our proposed project team includes individuals well known to the Corporate Environmental Affairs Department of Westinghouse. The key individuals are:

- Principal-in-Charge Mr. Patrick F. O'Hara
- Consulting Hydrogeologist Mr. Mark P. Zatezalo
- Senior Project Engineer Ms. Beth F. Cockcroft

The participation of additional professional staff members is anticipated, however, the initial phases of the environmental assessment will be conducted principally by the above three individuals. Mr. William J. Johnson and Dr. David A. Dzombak may also participate in this project. Mr. Johnson and Dr. Dzombak prepared the original Area A-9 Remedial Action Plan and contract documents for executing that plan. Mr. O'Hara and Mr. Zatezalo also participated in our previous work at the Beaver Facility. Ms. Cockcroft is an environmental engineer with extensive experience in assessing groundwater contamination. She serves in a similar role on our project at the Westinghouse Elevator Plant in Gettysburg, Pennsylvania, which also addresses alleged low-level TCE contamination of an aquifer over a fairly wide area.

WPL 005 5601

SET 0020639

SUITE 300, 10 DUFF ROAD, PITTSBURGH, PA 15235, PHONE: (412) 242-7900. TELEX: 882225

We propose to undertake this assessment in a series of tasks. These tasks are as follows:

2

- <u>Task 1 Initial Project Meeting</u> This task took place on July 13, 1988. Rizzo Associates has elected not to invoice Westinghouse for participation in this meeting.
- Task 2 Independent Observation of Field Sampling by the PADER This task has been completed. Rizzo Associates assigned a Senior Project Engineer to independently observe and document sampling practices employed by the PADER as well as the Westinghouse independent laboratory. In addition, our representative visited and investigated the open gravel pit immediately upgradient from the Vanport well field near the car dealership. Our representative obtained a sample of water believed to be discharged from this dealership into the gravel pit.
- Task 3 Participation in a Project Meeting with PADER and Preparation of an Initial Work Plan for the Performance of the Study This task has been completed.
- Task 4 Review of Existing Analytical Data from Investigations Performed by both PADER and Westinghouse Independent Laboratories This task will determine to the maximum degree practicable using existing data, which organic substances are present various sampling points. The reasoning for performing this task is to try to establish in general terms the relative likelihood of various contributors to current conditions observed at the Vanport Municipal well field and to verify that the alleged conditions are actually as reported. This task will be completed by August 30, 1988, assuming timely receipt of the required data.
- Task 5 Prerequisites to Remedial Investigation Under this task, Rizzo Associates will prepare the technical submittal documenting how the subsurface exploration program previously transmitted to the PADER for investigation of inorganic contamination at the Westinghouse facility will be adapted for purposes of also assessing the nature and extent of volatile organics. In addition, Rizzo Associates will

WPL 005 5602

4

solicit proposals from qualified drilling subcontractors and with the approval of Westinghouse retain one of those proposers to conduct the investigation described in the submittal mentioned above.

3

• Task 6 - Confirmatory Sampling of Wells in the A-9 Area

Rizzo Associates will send a sampling team to the Beaver Facility to obtain an additional round of groundwater samples. It is anticipated that the NUS Laboratory will be used to perform these analyses, and that NUS will bill its laboratory costs directly to Westinghouse. is also anticipated that NUS will provide containers and coolers for obtaining the samples and also provide a sample to be used as a trip blank and sufficient containers for the acquisition of a field blank and duplicate(s). Rizzo Associates will obtain the sample containers at the NUS Laboratory enroute to the Beaver Facility and will deliver the samples, maintaining proper chain of custody, to the NUS Laboratory receiving area upon completion of this task.

- Task 7 Subsurface Exploration Program and Installation of Additional Monitoring Wells Rizzo Associates will conduct the subsurface investigation and well installation program described in our Revised Remedial Action Plan of March 1987, as modified by our letter of July 27, 1988 to Ms. Linda LeGoullon. Rizzo Associates will perform the following:
 - Drill pilot borings for determining proper placement of monitoring wells.
 - Install monitor wells at the five additional locations depicted in the Revised Remedial Action Plan.
 - Develop the new monitoring wells.
 - Acquire field data as regards subsurface conditions and monitoring well installation.
 - Implement the health and safety plan for this activity.

WPL 005 5603

DCS

Rizzo Associates will obtain the soil and groundwater samples required under the sampling program and deliver those samples to the NUS Laboratory for analyses.

4

Task 8 - Data Analyses and Report Preparation Rizzo Associates will assess the results obtained during the performance of the subsurface investigation, and will obtain, evaluate, and summarize laboratory data generated by NUS as regards this sampling and analyses program. A technical report will be prepared which documents the information obtained in this supplementary remedial investigation. The report will describe the methodology and procedures utilized in the study, factual data obtained in the performance of the study, and an interpretation and assessment of the nature and extent of contamination in the A-9 area. In addition, the contamination with regards to possible sources within the Westinghouse Plant as well as possible impacts upon the Vanport Municipal Well Field will be evaluated. It is possible that at the end of this task the "answer" regarding the nature of impacts (if any) of the Westinghouse facility upon the Vanport Wells will not yet be conclusive. However, it is expected that sufficient data will be obtained to proceed with remedial activities as regards the contamination in Area A-9.

Task 9 - Meetings

Rizzo Associates proposes to participate in two meetings to be held either at the PADER or at the Westinghouse Building in Gateway Center. Participation in these meetings will include the Principal-in-Charge, the Consulting Hydrogeologist, and the Sr. Project Engineer.

ESTIMATED COSTS

Estimated costs shown for this project are depicted in Tables 1 through 4.

The total estimated cost for our performance of Tasks 1 through 9 as described above, are \$50,928. We anticipate contract terms and conditions consistent with those employed on our other similar projects for Westinghouse Environmental Affairs.

WPL 005 5604

Ms. Linda LeGoullon

In closing, we appreciate your confidence and trust. We hope this proposal is responsive to your needs. Please contact Ms. Beth Cockcroft or the undersigned should you have any questions on this transmittal.

Respectfully submitted, Patrick F. O'Hara Vice President

REPORT HYDROGEOLOGIC STUDY AREA A-9 - BEAVER FACILITY WESTINGHOUSE ELECTRIC CORPORATION

1.0 INTRODUCTION

This report summarizes the results of a field investigation conducted by Paul C. Rizzo Associates, Inc. (Rizzo Associates) in Area A-9 of Westinghouse Electric Corporation's Beaver facility. Previous studies (Rizzo Associates, 1985 and 1986a) documented the presence of localized perched zones of both high-pH and low-pH groundwater containing silver and cyanide. Groundwater samples collected by the Pennsylvania Department of Environmental Resources (PADER) and Westinghouse during June and July 1988 indicate that volatile organic compounds (VOCs) are also present in the subsurface in Area A-9.

The scope of work for this study was consistent with the March 12, 1987 Revised Remedial Action Plan (Rizzo Associates, 1987) and Modifications to Revised Remedial Action Plan (Rizzo Associates, 1988). The purpose of the investigation was to:

- Acquire information on the nature and extent of inorganic constituents in the subsurface of the A-9 area;
- Obtain data on the groundwater flow direction in the deep saturated unit associated with the soil-bedrock interface;
- Gather data on the nature and extent of VOCs in soil and perched groundwater in the A-9 area; and
- Obtain information on the occurrence of VOCs in the saturated unit associated with the soilbedrock interface.

WPL 005 5619

L Z

Included in the investigation were drilling, sampling, and chemical analysis of soils samples from ten borings; installation of five new monitoring wells; chemical analysis of groundwater samples from new and existing wells; and the abandonment of two wells.

2.0 SITE HISTORY AND RESULTS FROM PREVIOUS INVESTIGATIONS

The Beaver facility was originally operated by Curtiss Wright during World War II to manufacture airplane propellers. In the area currently known as A-9, a building bay existed which was used to access railroad cars outside the actual plant structure. After purchase of the plant by Westinghouse, Area A-9 was constructed in 1953 by placing a floor over approximately four feet of backfill and enclosing the area.

Although it is currently used as a steel drum staging area, Area A-9 was once used by Westinghouse for electroplating copper and aluminum bus bars with silver. Wastes from the operation were temporarily stored in five brick-lined, reinforced concrete holding tanks located approximately 20 feet outside of the plant, south of Area A-9. The acid and cyanide rinsewaters were piped directly to separate tanks which functioned as equalizer tanks prior to piping the rinse water to the onsite treatment facility. Acid, cyanide, and alkaline wastes were also piped to separate holding tanks and collected by a transporter for offsite disposal.

In 1983 seepage of acidic liquid was noted in the vicinity of the acid waste tank and in October 1983 a subsurface investigation was conducted around the tanks to investigate the leakage. Analysis of samples taken from one of the borings, B-4 (Figure 1), detected low pH (<3) groundwater adjacent to the acid waste tank (see Table 11). In a fifth boring drilled during November 1983 (Boring B-1A), a high (>10) pH groundwater containing cyanide was encountered.

In January 1984 the outside storage tanks were emptied and their use was discontinued. Two additional borings were drilled during February 1984, one encountering high pH fluids (Boring B-1B) and the other showing no anomalies (Boring B-2B). During July 1984, the pipelines connecting the

WPL 005 5621

3

plant facilities with these tanks were either plugged or removed and new PVC lines were installed to convey acid and cyanide rinsewater directly from the sumps to the wastewater treatment plant bypassing tank storage.

The outside storage tanks were removed during June of 1985. Following removal, the soil under the tanks was sampled, analyzed, and found to contain cyanide. As a result of these findings, an investigation of the area was undertaken to assess conditions of concern more fully. A deep boring (B-5) and three shallow borings (B-6, B-7, and B-8) were drilled during October 1985. Results from this study are presented in Rizzo Associates' May 28, 1986 report (Rizzo Associates, 1986a) which was submitted to PADER in June of 1988. Principal findings of this investigation were:

- Two distinct water-bearing zones underlie the A-9 Area. These zones are 1) a zone of perched groundwater at depths from 10 to 25 feet having highly variable characteristics over very short horizontal distances; and 2) a zone of saturation associated with the soil-bedrock interface at a depth of approximately 70 feet.
- Two distinct types of highly localized effects were confirmed in the perched groundwater zone. The findings of the earlier investigations regarding two distinct types of effected perched water ("high pH and low pH") were confirmed.
- The horizontal and vertical extent of the perched water having constituents of concern were further defined but not fully bounded.
- Groundwater samples from the zone of apparent continuous saturation associated with the soilbedrock interface (Well B-5) were not adversely impacted by the inorganic constituents detected in the overlying perched groundwater zone.

In order to mitigate the potential for off-site transport of contaminants in the perched groundwater zone, long-term pumping of Wells B-1B, B-4, and B-6 began in June 1986. A comprehensive remedial action

WPL 005 5622

DCS

4

plan was prepared by Rizzo Associates (Rizzo Associates, 1986b) and submitted to PADER in July 1986. At the request of PADER, a revised remedial action plan was prepared (Rizzo Associates, 1987) and submitted to PADER in March 1987. The revised plan included an investigative portion to define the extent of inorganic contamination and a section identifying remedial actions. PADER did not approve or provide comments on the revised remedial plan.

Groundwater samples from both groundwater zones were collected and analyzed for organic compounds by the PADER and Westinghouse during June and July 1988. VOCs were detected in samples taken from wells which monitor perched groundwater and from the zone of continuous saturation associated with the soil-bedrock interface. Because of the occurrence of VOCs, a modification to the investigative portion of the Revised Remedial Action Plan (Rizzo Associates, 1988) was made to include an assessment of VOCs. This report presents the results of that investigation.

5

WPL 005 5623

 \mathbb{D}

3.0 DESCRIPTION OF FIELD INVESTIGATION

The field investigation was performed following procedures described in the Revised Remedial Action Plan (Rizzo Associates, 1987) and Modifications to Revised Remedial Action Plan (Rizzo Associates, 1988) as conditionally approved by PADER on August 10, 1988. The planned investigation included drilling borings to better define the thickness and extent of the perched water bearing zones encountered in previous investigations. Initial boring locations were to the south and southwest of Area A-9 in what was believed to be the fringe of the area of inorganic interest. Field tests were performed on soil samples to determine pH and the presence of cyanide and VOCs. If field tests indicated subsurface cyanide and/or VOCs, additional boring(s) were to be drilled on Westinghouse property further from the A-9 area, to attempt to delineate limits of contamination.

At the outer limits of contamination (or edge of the property line), shallow wells were planned to be installed to monitor the perched groundwater. Wells were not to be installed when there was contamination as determined by the field screening tests or when there were no water bearing zones encountered. Borings at which no wells were to be installed were sealed by tremie grouting.

In addition to the shallow wells, two monitor wells were planned to be installed to define and monitor groundwater quality in the first zone of continuous saturation, i.e., the zone monitored by Well B-5 associated with the soil-bedrock interface. These wells were located such they could be used in conjunction with existing Well B-5 to determine the hydraulic gradient in the saturated zone overlying bedrock.

Selected soil samples collected during the field investigation were analyzed at NUS Laboratories for inorganic and volatile organic parameters. Groundwater samples were also collected from existing and newly-installed monitoring wells during the investigation and analyzed at the laboratory.

WPL 005 5624

DCS

6

The investigation was completed as planned with minor exceptions to accommodate conditions as actually encountered. This section describes the actual performance of the field investigation.

3.1 DRILLING AND SOIL SAMPLING

The drilling program consisted of a total of 10 soil borings. Three of these were drilled to bedrock. The remaining seven were shallow borings intended to define conditions in shallow subsurface. Boring locations are shown on Figures 1 and 2. Drilling was performed by Terra Testing and supervised by Rizzo Associates.

3.1.1 Drilling and Soil Sampling Methods

A CME 55 truck-mounted drill rig was used to advance 4 1/4-inch I.D., eight-inch O.D. continuous flight hollow-stem augers. Soil samples were collected with two-inch diameter split barrel Standard Penetration Test (SPT) samplers driven with a 140-pound hammer falling freely through a height of 30 inches. The number of blows required to drive the sampler each six inches for a total depth of 24 inches was recorded.

Geotechnical samples were collected on 2.5-foot centers from ground surface to the bottom of each boring. At Boring B-12, samples were collected at five-foot centers after the first 20 feet. The riser on Well B-12 was inadvertently damaged after well construction. Because the well could not be properly sampled, a replacement well (B-12A) was drilled 11 feet away. Soil samples were taken at 10-foot centers from Boring B-12A.

3.1.2 Soil Sample Collection and Analysis

After visual inspection and geotechnical classification of the split barrel soil samples, a geotechnical sample was collected and placed in a properly labeled glass jar. Geotechnical descriptions are summarized in

WPL 005 5625

the boring logs included as Appendix A. A sample jar from/the analytical laboratory, NUS, was also filled for selected soil samples to analyze for soil pH, cyanide, silver, sulfate, nitrate, and chloride concentrations in accordance with the Revised Remedial Action Plan.

In addition to laboratory testing, field tests were performed on the soil samples. An approximate soil pH was determined on a 1:1 soil/water slurry. The slurry was prepared by combining roughly 15 ml of soil and 15 ml of distilled water and shaking the mixture in a closed jar for approximately two minutes. Litmus paper was then used to determine the soil pH.

For soil samples with a pH greater or equal to seven, a 1:10 soil/NaOH solution slurry was prepared for cyanide analysis by combining 10 ml of soil with 100 ml of 0.01 Molar NaOH and mixing in a closed jar for approximately two minutes. The mixture was then allowed to settle for several minutes prior to filtering through a 0.5 micron filter using a hand operated vacuum pump. Hach Cyanide Test Kit procedures were followed on the filtered water. The color of the water after adding the reagents was compared to the value on the color comparator disc. The color disc reads values from 0 to 0.3 mg/l of free cyanide. A few cyanide tests were also performed on soil samples with pH less than seven as a spot check.

A field headspace reading was also performed on each soil sample by placing a piece of aluminum foil tightly over the lip of the sample jar, waiting approximately two minutes, breaking the aluminum foil seal with the HNu probe, and recording the peak response from the instrument. The soil sample having the highest headspace reading from each boring was sent to NUS labs to be analyzed for the VOCs on the Target Compound List. All samples for laboratory analysis were placed in a cooler on ice and delivered to the NUS laboratory for analysis.

WPL 005 5626

8

3.1.3 Equipment Decontamination

he drilling rig, tools, augers and related equipment were cleaned upon entering the site at an on-site decontamination area. The decontamination area consisted of several layers of plastic sheeting placed on concrete. Water falling on the sheeting drained into a sump and from there was pumped into barrels. The decontamination procedure consisted of steam cleaning with a Liquinox detergent solution followed by steam cleaning with potable water. Potable water used on site was obtained from the water system serving Terra Testing's shop. The steam cleaning procedure was performed as needed to ensure that clean augers, rods, and drill bits were used at each boring. Steam cleaning was also performed at the end of the job on all equipment.

Split barrel samplers were cleaned at the drill site after each use. The procedure consisted of a Liquinox detergent solution scrub, spraying with methanol, a potable water rinse, and spraying the sampler with distilled water.

3.2 MONITORING WELL INSTALLATION

Six monitoring wells were installed as part of this investigation. Installation diagrams for these wells provided in Appendix B. Three of these (B-9B, B-10A, and B-11) were installed to monitor the perched water zone. It was recognized during drilling that these wells would be marginal in terms of yield. However, they were installed to document the limits of perched water and could yield representative samples of the perched zone in "non drought" conditions. Borings B-12 (and its replacement B-12A) and B-13 were completed as wells to monitor the groundwater zone associated with the soil-bedrock interface. No wells were installed at Borings B-9, B-9A, B-10, and B-14. Borings B-9 and B-10 were grouted because soil headspace readings indicated that they were not beyond the limits of VOC contamination. Borings B-9A and B-14 were grouted because of insufficient water to set a well.

WPL 005 5627

9

Monitoring wells were constructed with two-inch I.D., threaded, flush joint, Schedule 40 PVC riser pipe and two-inch I.D., threaded, flush joint, Schedule 40 well screen with No. 10 (0.010-inch) slots. The PVC pipe at Boring B-12 was damaged at a depth of 11.5 feet from the ground surface after well construction. Therefore, when replacing the damaged well with B-12A, a 20-foot section of stainless steel riser pipe was joined to the PVC riser adjacent to the depth where damage occurred.

A bentonite seal was installed at the bottom of Borings B-9B, B-10A, and B-11 prior to placement of well screen and riser pipe to mitigate the potential carry-down of chemical constituents. Well screen and riser pipe were lowered inside the hollow-stem augers. After the riser pipe and well screen were positioned at the appropriate depth, Best Sand's No. 430 coarse silica sand was placed to a depth of one to two feet above the top of the well screen. A three-foot bentonite seal was placed above the sand pack. The remaining annular space was tremie grouted with a cement bentonite mixture consisting of one 94-pound bag of cement, seven gallons of water and between three and five pounds of bentonite. This mixture was also used for grouting in borings where wells were not set. A locking six-inch I.D. steel protective casing set in a concrete pad completed the installation. For Well B-12A a 7 1/2inch I.D. flush mounted steel protective casing with locking PVC cap was used due to traffic.

Monitoring wells were developed by bailing with stainless steel bailers. Complete well evacuation was achieved or a minimum of seven well volumes were removed from each well. Bailers used for well development were cleaned prior to each use with a Liquinox detergent scrub, a potable water rinse, spraying with methanol, followed by spraying with distilled water.

3.3 WELL ABANDONMENT

Wells B-8 and B-12 were abandoned during the installation program. Well B-8 had been installed as part of the previous investigation and

WPL 005 5628

10

never yielded sufficient water for sampling. Well B-12 was damaged and could not be properly sampled. The abandonment procedure consisted of pulling out the protective steel casing, PVC riser, and PVC screen; drilling out the hole with hollow-stem augers; and tremie grouting the hole with cement-bentonite grout. Because the PVC riser and screen could not be pulled out at Well B-12, it was drilled out with a hollowstem auger and the hole was tremie grouted.

3.4 GROUNDWATER SAMPLING

After the new monitoring wells were installed, groundwater samples were collected from Wells B-1, B-1A, B-4, B-5, B-6, B-7, B-12A, and B-13 (October 13, 1988). Samples were not collected from Wells B-1B, B-2B, B-9B, B-10A, and B-11 because of insufficient water encountered during this sampling event. A sampling team from the PADER was present to collect split samples.

Prior to sample collection three well volumes were removed from Wells B-12A and B-13. Because B-4 and B-6 are routinely pumped and the water treated by Westinghouse, purging was not performed prior to sampling. Wells B-1, B-1A, B-5, and B-7 were not purged prior to sampling because they contained a very small amount of water and they recharge very slowly. Before removing water from the wells, the static water level in each well was measured with an M-scope to establish the potentiometric surface and to determine the well volume. The M-scope was cleaned after each use by spraying with distilled water and wiping with a paper towel.

Purging and sampling equipment consisted of stainless steel bailers lowered and raised using polypropylene rope. Each bailer was decontaminated prior to use by first wiping its surface with an acetone saturated cloth, followed by a Liquinox detergent solution scrub, a potable water rinse, spraying with methanol and spraying with distilled water. Bailers were wrapped in aluminum foil immediately after decontamination and were unwrapped just prior to use. The sample from Well B-4 was obtained by means of peristaltic pump tubing because the blocked casing prohibited lowering a bailer into the well.

WPL 005 5629

BCS

Samples from Wells B-12A and B-13 were analyzed for sulfate, nitrate, chloride, and Priority Pollutants excluding herbicides, pesticides, and PCBs. Because of the small volume of water in Wells B-4, B-6, and B-7, only VOA vials could be filled and were analyzed for Priority Pollutant VOCs. Well B-1 had sufficient water to analyze for Priority Pollutant Metals and VOCs. Well B-1A had sufficient water to analyze for cyanide, and sulfate. Water from Well B-5 was analyzed for Priority Pollutant VOCs and cyanide. Samples were also analyzed in the field for pH, specific conductance, and temperature when there was sufficient volume to do so.

A field blank was collected on site by filling a clean bailer with distilled water. The water (rinsate) was then transferred to the sample bottle. This procedure was repeated until all bottles were filled. Specific conductance, pH, and temperature were measured and recorded at the time of collection. A trip blank for VOC analysis was prepared by the lab and was stored with the other samples. A duplicate sample was collected from Well B-13. All samples were stored in a cooler on ice immediately after sample collection and delivered to the NUS lab on the same day as sample collection.

A second sampling round occurred approximately six weeks after the first round (December 1, 1988). Samples were collected from the newlyinstalled wells. Wells B-9 and B-10A were dry. Samples were collected from Wells B-12A and B-13 using the same procedure as for the first round and were analyzed for Priority Pollutant VOCs. In addition, Westinghouse opted to collect samples from Wells B-1 and B-1A. PADER representatives collected a split sample from Well B-12A.

3.5 HEALTH AND SAFETY

To protect against equipment hazards and possible dermal exposure to hazardous substances during drilling, well installation, and well abandonment, site personnel wore disposable coveralls, steel toe boots, boot covers, inner gloves, outer gloves, safety glasses, and a hard

WPL 005 5630

DCS

12

hat. Boot covers and outer gloves were decontaminated after use with a soapy water scrub. Disposable coveralls and inner gloves were double bagged and were disposed in accordance with applicable requirements.

To monitor possible inhalation exposure, an HCN gas monitor and an HNu meter were used to monitor the breathing zone in the work area during drilling operations. No HCN or organic vapors were measured in the breathing zone, therefore, respiratory protection was not utilized.

3.6 MANAGEMENT OF RESIDUE

Drill cuttings, decontamination water, and purge water were collected and placed in labeled 55-gallon drums, sealed, and transported to an onsite staging area in the hazardous materials section of the plant. Material determined to be hazardous based upon laboratory analysis will be transported to a licensed waste disposal facility.

WPL 005 5631

4.0 HYDROGEOLOGIC ANALYSIS

4.1 HYDROGEOLOGICAL SETTING

The Westinghouse Plant in Beaver, Pennsylvania is located adjacent to a large alluvial terrace overlooking the Ohio River. As the glacial ice sheets terminated their southern movement about 10 miles north, glacial till is not a constituent of the terrace and nearly all of the sediments are alluvial in nature. Regional information concerning terraces along the Ohio River indicates that the terrace deposits consist of sand and gravel capped with about a 50-foot thickness comprised predominantly of silt. The alluvial aquifer associated with this terrace does not appear to be directly under the plant, but is reportedly present between the plant and the Ohio River, where the alluvium may be in excess of 150 feet thick.

4.2 SITE STRATIGRAPHY

The ten borings performed as part of this study allow for a more refined interpretation of site conditions than that presented in previous reports (Rizzo Associates, 1985 and 1986). Each of the stratigraphic units encountered at the site are described below.

4.2.1 Fill

Silt and clay to a thickness of 8 to 15 feet appear to be present irregularly across much of the plant, including Area A-9. Based on the visual classification of soil samples, the presence of rock fragments, cinders, brick fragments, etc., indicate that much of this surficial material is fill. Some sand and gravel beneath this material is also probably fill. Total fill thickness in Area A-9 ranges between 13 and 21 feet.

4.2.2 Fine Sand

A layer of orange to light brown, fine to medium sand found in all of the Area A-9 borings appears to represent the top of natural ground. This material is silty in places and occasionally contains rounded pebbles. The thickness of this unit varies between 13 and 19 feet.

WPL 005 5632

4.2.3 Sand and Gravel

The bedrock surface under the site is blanketed by a layer of sand and gravel which contains some silt, clay, and abundant angular rock fragments. This material is poorly sorted and may in part be colluvial in nature (i.e., material that has moved down slope from surrounding hillsides).

4.2.4 Bedrock

Borings to bedrock in different parts of the plant have encountered either sandstone or shale of the Pennsylvanian age Allegheny Group. Bedrock is frequently within 20 feet of the surface along the northwestern side of the plant. Sporadic borings in other parts of the plant indicate the bedrock surface is irregular, but generally deepens toward the Ohio River. Borings in Area A-9 indicated depths to bedrock of 63.5 feet at Boring B-5 and 88.5 feet at Boring B-12.

4.3 SITE HYDROGEOLOGY

Groundwater occurrence in the A-9 area includes both a perched water zone (<35 feet deep) and a saturated zone (60-80 feet) that occurs at or near bedrock. Hydrogeologic characteristics of these two zones are discussed below.

4.3.1 Perched Groundwater

The occurrence of perched groundwater in Area A-9 is erratic. The presence of between 10 and 20 feet of fill in Area A-9 helps explain the highly variable soil conditions and sporadic occurrence of perched groundwater. Most of the perched groundwater encountered appears to be present within the fill. It is probable that a very thin layer of relatively low permeability material separates these two zones, although such a layer was not confirmed during this investigation. In several borings, wet sand and gravel was observed to directly overlie essentially dry natural soils.

WPL 005 5633

 $\mathbb{D}\mathcal{O}\mathcal{S}$

Water levels in perched zones are currently significantly lower than those measured during December 1985 (Table 21 indicates measured depths to groundwater). This is likely the result of the continuous pumping and treating of the perched water that began in June 1986 as well as a decrease in precipitation over the past year.

4.3.2 Deep Saturated Unit

A deep saturated unit beneath Area A-9 occurs in silty and clayey sand and gravel immediately above the bedrock. The saturated thickness is less than 10 feet. Water level measurements from the three deep borings indicate that the groundwater flows in a southerly direction (toward the Ohio River) with possible discharge being into the alluvial aquifer mentioned in Section 4.1.

WPL 005 5634

5.0 CHEMICAL ANALYSIS RESULTS

5.1 SUBSURFACE SOIL

Selected soil samples were analyzed for the parameters described in Section 3.1.2. Tables 1 through 10 summarize the results from these analysis. The results of the analyses are discussed by type of parameter.

5.1.1 Volatile Organic Compounds (VOCs)

One or more of the VOCs 1,1-dichloroethene (1,1-DCE), 1,1,1trichloroethane (TCA), and trichloroethene (TCE) were found in samples taken from three of the ten site borings. Acetone and methylene chloride were also detected in several samples, but these substances are common laboratory contaminants and were often detected in laboratory blanks.

The highest TCE concentration was found in Boring B-9A in the wet sand fill above the dry natural sand. Also found in this sample were low concentrations of 1,1-DCE and TCA. In a sample 10 feet lower, within the dry natural sand layer, no TCE; 1,1-DCE; or TCA were detected. Headspace readings were higher in the natural sand layer, indicating VOCs occur in their gaseous state in this layer. TCA and TCE were also detected in the sand fill of Boring B-10. Levels just above the TCE detection limit were found in the sand and gravel fill of B-11.

5.1.2 Cyanide

Cyanide was detected in samples from the sand fill zone of Borings B-9 and B-11. These concentrations were significantly lower than those measured in samples taken from B-6 and B-7 during the previous investigation (Rizzo Associates, 1986a). Borings on the outer fringes of the study area (B-9A, B-9B, B-10, B-10A, B-12, B-12A, and B-14) showed no evidence of cyanide contamination. Figure 3 shows the approximate limit of anomalous cyanide concentrations in the soil.

WPL 005 5635

17

5.1.3 Silver

The highest silver concentration was measured in a sample taken from the fill layer in Boring B-11. All of the other soil samples showed concentrations less than or slightly above the detection limit.

5.1.4 pH

Soil pH values were consistent in samples taken from most of the new borings. A majority of soil samples pH values indicated slightly acidic conditions in the primarily dry silty clay/clayey silt fill. Neutral conditions occur in the wet sand and gravel fill and in the natural soil zones.

The only boring with unusual soil pH values was B-11. In this boring all samples, except one, were slightly basic. The sample taken in the moist sand and gravel fill was acidic.

5.1.5 Sulfate

Soil sulfate concentrations measured during this study were higher than for previous investigations. For most borings, concentrations were highest in the fill layer and decreased significantly in the natural sand layer. The upgradient boring, B-13, also had high soil sulfate concentrations, indicating that the values detected are probably not indicative of environmental contamination.

5.1.6 Nitrate

A few anomalously high nitrate values were measured in the fill material of Borings B-9A, B-12, and B-14.

5.1.7 Chloride

The only chloride concentration above the detection limit was found in the first two feet of the upgradient Boring B-13.

WPL 005 5636

DCS

5.2 GROUNDWATER

Section 3.4 describes the methods used to collect groundwater samples and the parameters for sample analysis. Results of these analysis are given in Tables 18 and 19. Analytical results for sampling performed by NUS during July 1988 are presented in Tables 16 and 17. Groundwater sampling data from previous investigations is given in Tables 11 through 15. The results of these analyses are discussed by type of parameter.

5.2.1 VOCs

TCE was detected in samples from all of the perched zone monitoring wells, with the highest occurrences in Wells B-1 and B-7. TCE was also detected in Wells B-5 and B-12A which monitor the deep saturated zone.

Other VOCs detected in most of the perched zone monitoring wells were 1,1-DCA; 1,1-DCE; and TCA. In addition to these compounds 1,1-dichloroethane (1,1-DCA); 1,2-dichloroethane (1,2-DCA); 1,2-dichloroethene (1,2-DCE); methyl chloride; methylene chloride; and toluene were erratically detected in perched zone monitoring wells. Methyl chloride, methylene chloride and toluene were detected infrequently and at low concentrations.

Because all of the wells sampled in the A-9 area contained TCE and related VOCs, the limits of occurrence could not be determined. Shallow wells on the fringes of the monitored area (B-9B, B-10A, and B-11) yielded insufficient water for sampling.

TCE was the only contaminant detected in the deep saturated zone (Wells B-5 and B-12A).

5.2.2 Cyanide

In previous studies, cyanide was detected in all of the wells monitoring the shallow perched water zone. No samples from new shallow wells were collected for cyanide analysis during this study because there was insufficient water in the new shallow wells (B-9B, B-10A, and B-11). The samples collected from the deep wells detected no cyanide.

WPL 005 5637

 $\mathbf{DC5}$

5.2.3 Other Parameters

Other analysis performed on samples from the new wells included acid and base neutral extractables, metals, chloride, nitrate, and sulfate. Results from these analysis showed no anomalous concentrations.

5.3 PADER SAMPLING OF VANPORT WELLS

PADER provided analytical results of the sampling of production and test wells in the Vanport Municipal Authority well field, and are presented in Table 20. This table shows concentrations of VOCs detected using a GC/MS scan. Results from the test wells differ significantly from the production wells. Test well samples contain ethyl benzene, methylene chloride, toluene, and xylene in addition to TCA and TCE. The methods PADER used to collect samples from the test and production wells are not known.

6.0 SUMMARY OF FINDINGS

A summary of the findings of this investigation is as follows:

- The perched groundwater zone appears to be very limited in extent in the A-9 Area. Of the 10 wells which monitor this zone, four are dry. Most of the remaining water producing wells can be bailed dry after removal of a very small quantity of water (less than 0.25 liters). This is believed to be a result of the ongoing pumping and treatment program for Wells B-1B, B-4, and B-6 and/or lack of precipitation.
- Chemical constituents of interest were detected primarily in moist or wet sand and gravel fill. This material is generally found at a depth of 10 to 20 feet from the ground surface. Analytical data do not indicate migration of inorganic constituents of interest into the unsaturated sand found beneath the fill.
- Various VOCs were detected in the perched groundwater zone. In addition to TCE and TCA, related compounds such as 1,1,-DCE; 1,1-DCA; 1,2-DCA; and 1,2-DCE were detected in the shallow wells. As VOCs were detected in a soil sample from the fill from Boring B-9A, the extent of this occurrence south of Area A-9 is not apparent. The shallow occurrence of VOCs appears to be bounded east of Area A-9 by Boring B-14 and to the west by Boring B-12.
- Cyanide appears not to have migrated from the plant site. The area currently known to be contaminated is a localized perched zone surrounded by borings showing no anomalous cyanide concentrations (B-9A, B-9B, B-10A, B-12, B-12A, and B-14). The approximate limit of anomalous cyanide concentrations is shown on Figure 3. Cyanide was not detected in the zone of continuous saturation associated with the soil-bedrock interface.
- Flow direction in the zone of continuous saturation is generally towards the river. The Vanport Water Authority well field is located adjacent to the bank of the Ohio River.

- Groundwater samples from the zone of continuous saturation in Area A-9 contain TCE at less than 1 ppm. Other VOC constituents detected in the perched groundwater were not detected in the zone of continuous saturation.
- VOCs were not detected in soil samples taken from the natural soil layers beneath the fill.
- Ethyl benzene was detected in the Vanport Municipal Authority wells in addition to toluene, xylene, TCE and related compounds. Ethyl benzene was not detected in any of the samples collected from the A-9 area. Of all the VOC constituents reported in the municipal well field, only TCE was detected in the zone of continuous saturation at Area A-9 of the Westinghouse property.

In summary, the occurrence of inorganic groundwater contamination in Area A-9 appears to be highly localized and has not been detected in continuous groundwater units. The inorganic constituents do not appear to extend to the property line. Past and ongoing remediation appears successful.

The occurrence of VOCs in shallow, discontinuous groundwater has been detected in Area A-9. The units monitored are highly localized both laterally and vertically, and the full extent of apparent contamination has not been bounded in one direction.

The occurrence of VOCs has been confirmed with respect to TCE. TCE was detected in the zone of continuous saturation beneath Area A-9. The samples obtained from this zone at the A-9 Area do not indicate the presence of other VOCs detected in the Vanport Municipal Wellfield nor in the overlying zone of perched groundwater.

Respectfully submitted,

Margaret a. Pelcher

Margaret A. Pelcher Asst. Project Enginear

Patrick F. O'Hara Vice President

		-			

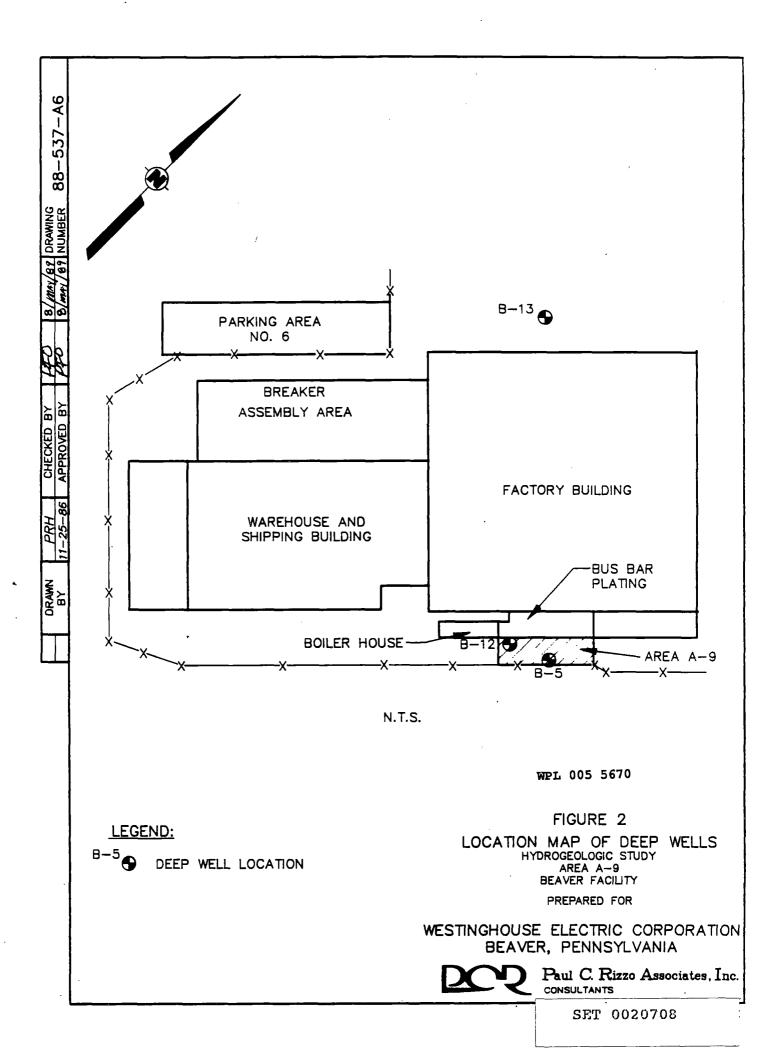

All depths to water measurements were measured from the top of the protective casing and are reported in feet. Wells B-5, B-12A, and B-13 were surveyed in April 1989. Any future reporting for these and other wells monitoring zones of relatively continuous saturation will be in feet above means sea level.
