DRINKING WATER NEWS

THE FACT, CHOICE, AND FUTURE OF DRINKING WATER

January 2021

The Pennsylvania Department of Environmental Protection (DEP) Bureau of Safe Drinking Water (BSDW) has released the [2020 Annual Report](#) and [2021 Priorities](#). Here are some highlights:

- Optimal Performance Ranges for Corrosion Control Treatment
- Cybersecurity in the Drinking Water Sector
- Flash Issues and the Impact on Public Water Systems – Take Time to Prepare
- Standard Monitoring Framework and the Monitoring Waiver Application
- Planning for Long-term System Maintenance and Aging Infrastructure
- When Cleaning Your Well or Filter With Chemicals, Pick Out a Permit
- Drought Contingency Plan
- Laboratory Reporting Requirements
- Chain of Custody Success – Where Are My Data?
- How Do I Get Started?

To ensure enhanced regulatory oversight of the utilities' [Chapter 291, Safe Drinking Water](#)

Optimal Performance Ranges for Corrosion Control Treatment

Dana Hoffman, Compliance Specialist, DEP Southcentral Region

Corrosion control treatment is a key component of a water system's treatment process. Corrosion control treatment is required by the Lead and Copper Rule (LCR) for water systems that have lead service lines, lead goosenecks, or copper pipes with lead solder. Corrosion control treatment is designed to minimize the amount of lead and copper that may be released into the water from plumbing materials. Corrosion control treatment is not required for water systems that do not have lead service lines, lead goosenecks, or copper pipes with lead solder.

Water systems that are required to install corrosion control treatment must operate in accordance with the optimal water quality parameters established by DEP. The optimal water quality parameters are the water quality conditions required to maintain minimal corrosion in the water system's distribution system and to form effective protective coatings on the interior surfaces of lead and copper pipes. The optimal water quality parameters are established by DEP after the water system has completed the applicable requirements of the LCR.

DEP staff monitor the water in a water system's system to see if it operates within the optimal water quality parameters established for the water system. Water systems must collect samples every six months at taps that are targeted for sampling. Water systems must also collect samples at entry points to the distribution system every two weeks. Water systems must measure the following water quality parameters: pH, alkalinity, orthophosphate, silica, calcium, conductivity, water temperature, and water pressure.

Water systems must report the results of all water quality parameter monitoring to DEP within 10 days after the end of the month in which the water system receives the results. DEP staff review the water system's water quality parameter monitoring results to ensure that the water system is operating within the optimal water quality parameters established for the water system.

- Recruitment of the operator(s) needed to monitor and maintain operation throughout the day(s).
- Training of the operator(s) to ensure they understand the importance of their duties and how to perform them correctly.
- Development of standard operating procedures (SOPs) to ensure consistent operation and maintenance.

Water systems must operate in accordance with the optimal water quality parameters established for the water system. Water systems must collect samples every six months at taps that are targeted for sampling. Water systems must also collect samples at entry points to the distribution system every two weeks. Water systems must measure the following water quality parameters: pH, alkalinity, orthophosphate, silica, calcium, conductivity, water temperature, and water pressure.

Water systems must report the results of all water quality parameter monitoring to DEP within 10 days after the end of the month in which the water system receives the results. DEP staff review the water system's water quality parameter monitoring results to ensure that the water system is operating within the optimal water quality parameters established for the water system.

Cybersecurity in the Drinking Water Sector

Dana Hoffman, Compliance Specialist, DEP Southcentral Region

In [Fact, Choice, and Future of Drinking Water](#), DEP identified cybersecurity as one of the [2021 Priorities](#). Cybersecurity is the practice of protecting systems, networks, and programs from digital attacks. Cyberattacks usually intend to access or destroy sensitive data and extort money from users or interrupt normal business processes.

Cybersecurity is a concern for water systems because water systems rely on computers to operate and control many of the processes involved in treating and distributing drinking water. Water systems also rely on computers to store customer billing information and employee records. Water systems must protect their computers from cyberattacks to ensure that they can continue to provide safe drinking water to their customers.

Water systems can take many steps to protect their computers from cyberattacks. Some of the steps that water systems can take are listed below:

- Identify the computers that are most important to the water system's operations.
- Develop a cybersecurity plan that describes how the water system will protect its computers from cyberattacks.
- Train employees on how to recognize and avoid cyberattacks.
- Use strong passwords and change them frequently.
- Install software that protects computers from viruses and other malicious programs.
- Keep software up to date with the latest security patches.
- Back up important data regularly and store it in a safe place.
- Monitor computer networks for suspicious activity.
- Have a plan in place for responding to a cyberattack.

By taking these steps, water systems can help protect their computers from cyberattacks and ensure that they can continue to provide safe drinking water to their customers.

Flash Issues and the Impact on Public Water Systems – Take Time to Prepare

Jill Andrews, Groundwater Survey Manager, Section Office

Flash issues are a common occurrence in Pennsylvania. Flash issues are defined as a rapid increase in the amount of water in a stream or river. Flash issues can be caused by heavy rainfall, snowmelt, or the failure of a dam or levee. Flash issues can be dangerous because they can sweep away people, vehicles, and buildings. They can also damage public water systems by contaminating their water supplies.

Public water systems can take many steps to prepare for flash issues. These steps include:

- Developing an emergency response plan that includes procedures for evacuating people and protecting property.
- Installing flood barriers or other structures to protect water supply infrastructure.
- Monitoring weather forecasts and river levels so that they can be aware of potential flash issues.
- Training employees on how to respond to flash issues.

By taking these steps, public water systems can help to minimize the impact of flash issues on their operations and on the communities they serve.

Standard Monitoring Framework and the Monitoring Waiver Application

Matthew Shaw, Groundwater Specialist, DEP Northcentral Region

Assets 35 - 39 of the [Fact, Choice, and Future of Drinking Water](#) report identify the need to develop a framework for monitoring waivers for inorganic chemicals (IOCs), volatile organic chemicals (VOCs), synthetic organic chemicals (SOCs), and radionuclides. This article will provide background information on the Safe Drinking Water Act (SDWA) requirements, the current monitoring waiver framework, and the proposed framework for the monitoring waiver application.

Table 1. Contaminant Monitoring Framework Schedule 2020-2027

Contaminant Group	Initial Monitoring	Repeat Monitoring	Reduced Monitoring
Inorganic Chemicals (IOCs)	2020	2023	2026
Volatile Organic Chemicals (VOCs)	2021	2024	2027
Synthetic Organic Chemicals (SOCs)	2021	2024	2027
Radionuclides	2020	2023	2026

The SDWA requires that all public water systems (PWSs) monitor for contaminants to determine compliance with maximum contaminant levels (MCLs). The SDWA also allows states to grant waivers from monitoring requirements for certain contaminants. The Pennsylvania Department of Environmental Protection (DEP) has developed a framework for monitoring waivers for IOCs, VOCs, SOCs, and radionuclides. The framework is based on the following principles:

1. Previous monitoring data
2. The likelihood that a contaminant is present in the water source
3. The vulnerability of the water source to contamination
4. The size of the PWS

The framework establishes a schedule for monitoring and waivers. The schedule is based on the principle that PWSs with a higher likelihood of contamination should monitor more frequently. The framework also establishes criteria for granting waivers. The criteria are based on the principle that PWSs with a lower likelihood of contamination should be granted waivers more easily.

The framework is expected to be implemented in 2021. The first PWSs to be eligible for waivers will be those that have completed their initial monitoring. The framework is expected to be fully implemented by 2027.

The framework is a significant change from the current monitoring requirements. The current requirements require all PWSs to monitor for all contaminants every three years. The framework will allow PWSs with a lower likelihood of contamination to monitor less frequently. This will save PWSs money and will allow DEP to focus its resources on PWSs that are more likely to have contamination problems.

The framework is a complex document. DEP will provide training and guidance to PWSs on how to implement the framework. DEP will also provide a monitoring waiver application that PWSs can use to request waivers.

Planning for Long-term System Maintenance and Aging Infrastructure

Andrew Wagner, Compliance Specialist, DEP Northcentral Region

Many of the challenges that water systems face today are the result of aging infrastructure. Water mains, pumps, and treatment plants that were built decades ago are now reaching the end of their useful lives. This can lead to a number of problems, including:

- Increased water loss due to leaks and breaks
- Reduced water pressure
- Poor water quality
- Increased energy costs
- Service disruptions

Water main break

To address these challenges, water systems need to develop long-term plans for maintaining and replacing their infrastructure. These plans should include:

- An inventory of the system's assets, including the condition and remaining useful life of each asset
- A prioritization of projects based on the risk of failure and the impact on the system's customers
- A financial plan that identifies the funding sources for the projects
- A schedule for implementing the projects

Water tower

Developing a long-term plan can be a complex and time-consuming process, but it is essential for ensuring the reliability and sustainability of a water system. There are a number of resources available to help water systems develop their plans, including:

- The Pennsylvania Department of Environmental Protection's (DEP) Bureau of Safe Drinking Water (BSDW) has a [Technical Assistance Center](#) that can provide free technical assistance to water systems.
- The [Pennsylvania Rural Water Association](#) (PRWA) offers training and assistance to water systems on a variety of topics, including long-term planning.
- The [American Water Works Association](#) (AWWA) has a number of publications and resources on long-term planning.

Water treatment plant

By developing a long-term plan, water systems can ensure that they are prepared for the challenges that they will face in the future. This will help them to provide safe, reliable, and affordable drinking water to their customers for many years to come.

When Cleaning Your Well or Filter With Chemicals, Pick Out a Permit

Jill Andrews, Groundwater Survey Manager, Section Office

Mount, shock or well disinfection is a process that is used to clean and disinfect a well or filter. This process involves the use of chemicals to kill bacteria and other microorganisms that may be present in the water. The chemicals are typically chlorine or a chlorine-based compound.

Well disinfection

The process is relatively simple, but it is important to follow the proper procedures to ensure that the chemicals are used safely and effectively. The first step is to determine the amount of chemicals that are needed. This is usually done by measuring the volume of the well or filter and then calculating the amount of chemicals that are needed to achieve the desired concentration.

Once the amount of chemicals has been determined, they are added to the well or filter and then circulated throughout the system. This is usually done by using a pump to recirculate the water. The chemicals are then allowed to remain in the system for a period of time, typically several hours or days, to allow them to kill the bacteria and other microorganisms.

After the chemicals have been allowed to remain in the system for the appropriate amount of time, they are then flushed out of the system. This is usually done by opening a valve and allowing the water to flow out of the system. The water is then tested to ensure that the chemicals have been removed and that the water is safe to drink.

Well disinfection is an important process that helps to ensure the safety of drinking water. It is important to follow the proper procedures to ensure that the chemicals are used safely and effectively.

By developing a long-term plan, water systems can ensure that they are prepared for the challenges that they will face in the future. This will help them to provide safe, reliable, and affordable drinking water to their customers for many years to come.

Why Flush Lines Using Only Raw Water Are Not Recommended

Nathan Reisinger, Groundwater Specialist, DEP Northcentral Region

Flushing is a process that is used to clean and disinfect water lines. It involves running water through the lines at a high velocity to remove sediment, debris, and microorganisms. Flushing can be done using either raw water or treated water. However, there are a number of reasons why flushing lines using only raw water is not recommended.

- Raw water may contain high levels of sediment, debris, and microorganisms. These contaminants can clog the lines and reduce the flow of water. They can also damage the lines and equipment.
- Raw water may contain pathogens that can cause illness. These pathogens can survive in the lines and contaminate the water that is used for drinking, cooking, and bathing.
- Raw water may contain chemicals that can react with the materials in the lines. This can cause corrosion and damage the lines.

Flushing lines using only raw water can be a waste of water. The water that is used for flushing is not treated and cannot be used for drinking, cooking, or bathing. This water is then wasted.

Flushing lines using only raw water can be a waste of money. The cost of treating water is high. Using raw water for flushing can increase the cost of operating a water system.

Flushing lines using only raw water can be a waste of time. The process of flushing lines can take a long time. Using raw water for flushing can increase the amount of time that it takes to flush the lines.

For these reasons, it is not recommended to flush lines using only raw water. Instead, water systems should use treated water for flushing. Treated water is safe to drink and will not damage the lines or equipment. It is also more cost-effective and time-efficient.

Laboratory Reporting Requirements

Laboratories are required to report certain information to DEP when they analyze samples for public water systems. This information is used to determine whether the water system is in compliance with drinking water regulations. The following is a list of the information that laboratories are required to report:

- The name and address of the laboratory
- The name and address of the public water system
- The date and time the sample was collected
- The date and time the sample was received by the laboratory
- The analytical method used
- The results of the analysis
- The detection limit for each analyte
- The quality control data for the analysis

Laboratories are required to report this information within 10 days of the end of the month in which the analysis was performed. Laboratories can report this information electronically or by mail.

Laboratories that fail to report this information may be subject to enforcement actions, including fines. DEP may also revoke the laboratory's certification.

Here are some additional resources that you may find helpful:
