Overview of Drip Irrigation

Chapter 1 — page 1 out of 14 pages

OVERVIEW OF DRIP IRRIGATION

- * What You Will Learn in This Chapter
- * Components of a Drip Irrigation System
- * Drip Irrigation Absorption Area Terminology
- * Advantages and Disadvantages of Drip Irrigation
- * Elements of Success in Drip Irrigation

The central graphic features a light yellow background with a list of five topics. To the left of the list is a large illustration of a two-story house with a brown roof and white walls. To the right is a smaller illustration of a single-story house with a brown roof and white walls. Several green trees of varying heights are scattered around the houses. The text is in a dark brown font, and the title 'OVERVIEW OF DRIP IRRIGATION' is in a large, bold, green font.

- * Aeration and Renovation
- * Components of Soil
- * Soil Porosity
- * Soil Texture and Structure
- * The Soil-Wastewater Relationship
- * Summary of Water Movement Through Soil

[NEXT](#) [Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

What You Will Learn in This Chapter

page 2 out of 32

- Drip irrigation applies wastewater in small, frequent doses, which maintains an aerobic environment in the soil.
- Two important soil characteristics direct water movement through a soil profile and influence the soil's ability to hold water against gravitational forces.
- The renovative capacity of soil is significantly enhanced when wastewater is applied at a rate that provides unsaturated flow.
- Soil morphological features are used to properly size a drip irrigation system, to promote an aerobic soil environment, and to improve wastewater renovation.

[← BACK](#)

[HOME](#)

[NEXT →](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Drip Irrigation Concepts

page 3 out of 32

Emitter in a Drip Irrigation System

- Frequent low-pressure applications of effluent to the soil result in conditions that promote wastewater renovation. A drip irrigation system provides this type of application.

- These frequent, small doses allow the soil to remain in an aerobic condition. Unsaturated flow occurs in this condition.
- During unsaturated flow, exchange sites in soil pores facilitate the chemical, physical, and biological processes that filter and renovate wastewater effluent.

[◀ BACK](#)[HOME](#)[NEXT ▶](#)[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Aeration and Renovation

page 4 out of 32

Unsaturated flow typically occurs in an aerobic environment.

Why is aeration important?

Wastewater has a BOD (biological oxygen demand). This is the quantity of oxygen used in the biochemical oxidation of organic and inorganic matter in a specified time, at a specified temperature, and in specified conditions. It is an indirect measure of the concentration of biologically degradable material present in organic wastes.

[◀ BACK](#)[HOME](#)[NEXT ▶](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Components of Soil

page 5 out of 32

In a typical soil, about **25%** of the volume is water and **25%** of the volume is air. The rest of the soil is made up of solid material, consisting of mostly mineral and a small amount of organic material.

[◀ BACK](#)[HOME](#)[NEXT ▶](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Porosity

page 6 out of 32

- Porosity is the component of a soil body that is not occupied by solid material (mineral or organic). It is the available pore space that is filled with air or water (about 50% in a typical soil).
- Porosity is influenced by **texture** and **structure**. These two soil characteristics have a direct influence on aeration, infiltration of water, and movement of water through the soil profile.

[← BACK](#)

[HOME](#)

[NEXT →](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Porosity

page 7 out of 32

Relative Pore Size

Macropores

These larger pore spaces are often **air** filled and they usually transmit water flow under saturated conditions.

Micropores

These smaller pore spaces fill first with water under unsaturated flow. Most renovation is associated with these micropores. Unsaturated flow provides improved wastewater renovation, which usually occurs in these pores.

[← BACK](#)[HOME](#)[NEXT →](#)[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Texture and Structure

page 8 out of 32

Listed below are two important soil characteristics that influence the aerobic conditions in soil:

Instructions: Click on the correct answer.

- ? Soil Texture ●
- ? Soil Structure ●
- is the relative percentages of sand, silt, and clay particles.
- ? Soil Texture ●
- ? Soil Structure ●
- is the combination or arrangement of soil particles into units or peds of recognizable shapes.

[◀ BACK](#)[HOME](#)[NEXT ▶](#)

[Back to the Table of Contents](#)

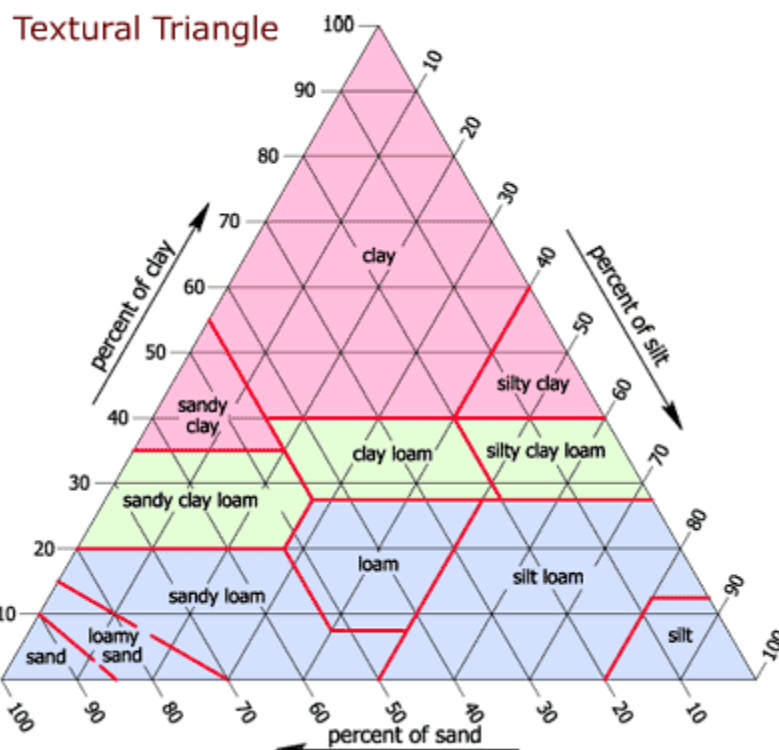

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Texture and Structure

page 9 out of 32

Texture

- Soil texture is the percent of sand, silt, and clay in a soil.
- Soil texture modifies water movement through the soil profile due to its influence on pore size.

[← BACK](#)
[HOME](#)
[NEXT →](#)
[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Texture and Structure

page 10 out of 32

Texture and Pore Size

Instructions: Click on the correct answer.

- Macropores** **Micropores** are associated with sandy textures.

Sandy soils are generally well-aerated soils, because the larger pores are typically filled with oxygen from the atmosphere. This texture is low in total porosity, yet individual pore sizes are large.

- Macropores** **Micropores** are associated with silt and clay textures.

Silty and **clayey** soils are generally less-aerated, because the smaller pores may be filled with water. These textures are high in total porosity, yet individual pore sizes are small.

[◀ BACK](#)[HOME](#)[NEXT ▶](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Texture and Structure

page 11 out of 32

Texture and Pore Size

The rate of water movement is directly related to **pore size**.

Texture also affects the amount of air and water present in the soil.

[← BACK](#)[HOME](#)[NEXT →](#)[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Texture and Structure

page 12 out of 32

Structure

- Structure is the combination or arrangement of primary soil particles (sand, silt, and clay) into secondary units or peds.
- These secondary units provide an additional network of macropores and micropores. Structural units further influence the content and movement of air and water in the soil.
- The individual structural units can be categorized by general types or shapes, which may determine the rate of water flow through the soil.

[← BACK](#)[HOME](#)[NEXT →](#)[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Texture and Structure

page 13 out of 32

Granular Structure

- Granular structure typically occurs close to the surface of the soil.
- The spherical granules generally do not pack tightly, primarily leaving macropores between individual structural units.
- Water flow is usually good, aeration is good, and wastewater renovates well in this structure.

[◀ BACK](#)[HOME](#)[NEXT ▶](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Texture and Structure

page 14 out of 32

Angular and Subangular Blocky Structure

- These structures are block-like in shape with either angular or rounded edges.
- As the units pack together, they have more micropores and fewer macropores than granular structure.
- Angular and subangular blocky structures are good for water movement and aeration and provide good hosts for wastewater renovation.

Subangular Blocky Structure

Subangular Blocky Structure

[◀ BACK](#)[HOME](#)[NEXT ▶](#)[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

Soil Texture and Structure

page 15 out of 32

Prismatic and Platy Structures

- These structures have reduced water movement and poor aeration.
- Platy structure has a long horizontal axis, and prismatic structure has a long vertical axis.
- These structures are not desirable for soil horizons receiving wastewater.

Platy structure

Prismatic structure

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

The Soil-Wastewater Relationship

page 19 out of 32

Natural Forces That Affect Water Flow Through Soils

- **Gravitational** forces result in the downward movement of water in saturated flow.
- **Matric** forces are the cohesive and adhesive forces that result in capillary action during unsaturated flow. Capillary action is the ability of water to move against the force of gravity.
- **Osmotic** forces involve the chemical interaction between ions occurring in soil and water.
- Gravitational forces pull the water **downward**, matric forces may pull the water in **any** direction, and the osmotic forces are associated with any corresponding **chemical** reactions. All of these forces affect the flow of wastewater through soil.

Drip Irrigation-Sewage Renovation

Chapter 3

The Soil-Wastewater Relationship

page 21 out of 32

Water Movement Through Soil

The two flows that affect wastewater renovation:

- **Saturated** flow - Water movement without adequate renovation.
- **Unsaturated** flow - Water movement with adequate renovation.

[← BACK](#)[HOME](#)[NEXT →](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

The Soil-Wastewater Relationship

page 22 out of 32

Saturated Flow

- Saturated flow refers to the movement of water through soil that typically occurs in the macropores.
- Saturated flow results when micropores and macropores are filled with water and gravitational forces overcome the capillary forces associated with adhesion and cohesion.

The water flows downward through the soil driven by gravitational force in an anaerobic condition. Wastewater under saturated flow creates an anaerobic environment.

- Is this environment conducive to good wastewater renovation?
Exchange sites are occupied by water molecules in the micropores when soils are saturated. Consequently, the renovation of effluent is significantly **reduced** during saturated flow.

[← BACK](#)[HOME](#)[NEXT →](#)[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

The Soil-Wastewater Relationship

page 23 out of 32

Unsaturated Flow

- Unsaturated flow results when the soil moisture content is below field capacity. Field capacity occurs when the matric and gravitational forces are equal. When the two forces are equal, the soil is able to hold onto or adsorb the water.
- **Adsorption** – The process by which atoms, molecules, or ions are taken up from the soil solution or soil atmosphere and retained on the surface of solids by chemical or physical binding.
- When water is held in the soil, it remains in contact with the exchange sites. Typically, chemical and biological reactions occur at these sites.
- Water movement through these micropores during unsaturated flow results in improved renovation.
- Unsaturated flow almost always occurs under aerated soil conditions. When soil conditions are aerobic, the renovative capacity of the soil is **improved**. Air is also available to assist with the breakdown of organic materials found in wastewater.

[◀ BACK](#)[HOME](#)[NEXT ▶](#)[Back to the Table of Contents](#)

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3

The Soil-Wastewater Relationship

page 24 out of 32

Summary of Water Movement Through Soil

Unsaturated Flow

This flow occurs through the micropores, and it allows a longer retention time in the soil for bacteria and virus to die off. Consequently, there will be little or no migration of these organisms.

Saturated Flow

This flow occurs when the micropores are filled and the wastewater moves through the macropores of the soil. Bacteria and viruses travel along with the wastewater through these macropores. This flow may not allow the retention time necessary for the decay of anaerobic organisms and the corresponding organic decomposition that occurs in an aerobic environment.

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3 **Summary of Water Movement Through Soil** page 29 out of 32

Water Flow Through the Soil Using a Drip Emitter

After 750 minutes of constant flow, most of the soil pores are filled, resulting in increased saturated flow. Capillary action is no longer pulling the wetting front up as gravity overcomes the soil's adhesive and cohesive forces and pulls the wetting front down.

Summary of Water Movement Through Soil

page 30 out of 32

Water Flow Through the Soil Using a Drip Emitter

This picture shows the wetting front for a drip irrigation system. The drip emitter has not been run constantly in this model but has been dosed and allowed to rest between doses. Note the difference in the wetting front for a drip irrigation system compared to the previous photos.

Unsaturated flow is pulling the wetting front laterally and upward. Below the emitter, there is a reduced area of saturated flow. The dosing allows for a greater percentage of the wetting front to be in an unsaturated condition.

Drip Irrigation Training Course

Drip Irrigation-Sewage Renovation

Chapter 3 Summary of Water Movement Through Soil page 32 out of 32

Review

- Drip irrigation distributes frequent, small doses of wastewater evenly throughout a large area. Consequently, this sustains an **CORRECT!** / **aerobic** environment in the soil where wastewater is more effectively treated. The corresponding unsaturated flow of wastewater through soil yields improved renovation.
- Drip irrigation takes maximum advantage of the soil's **natural porosity** / **CORRECT!** and maintains an aerobic environment, which improves permeability and encourages BOD reduction. This system also promotes optimal unsaturated flow conditions and provides the retention time needed for bacteria and virus to die off.

Primary Treatment

page 6 out of 13

Sections 73.31 and 73.32

Two Options:

1) Septic tank(s)

- The septic tank or tanks for a drip system must meet all the requirements of the Department of Environmental Protection regulations regarding onlot sewage systems.

2) Aerobic tank

- An aerobic tank must be approved by the National Sanitation Foundation (NSF) as specified in the Department of Environmental Protection regulations regarding onlot sewage systems, or it must be a department-approved tank.

Note: The designer may choose either primary treatment option to use in a drip irrigation system design.

Drip Irrigation Training Course

System Components — Hydraulic Unit**Chapter 4 B****Hydraulic Unit**

page 7 out of 10

Maximum Specifications:

After the drip zones are designed, then the hydraulic unit (either a two-disc filter or a three-disc filter) that meets the design requirements may be chosen. The maximum specifications for each unit are listed below.

Two-disc filter unit:

- ✓ Max. 1,200 feet of tubing per zone
- ✓ Max. 15 gpm = tubing forward field flush flow rate
- ✓ Max. 5 lateral connections
- ✓ Max. 4 zones
- ✓ Max. 4,800 feet of tubing

Three-disc filter unit:

- ✓ Max. 2,400 feet of tubing per zone
- ✓ Max. 25 gpm = tubing forward field flush flow rate
- ✓ Max. 8 lateral connections
- ✓ Max. 16 zones
- ✓ Max. 38,400 feet of tubing

Chapter 4 B

Hydraulic Unit

page 8 out of 10

Hydraulic Conditions:

- A hydraulic condition is a name given to a certain flow and its direction. There are three hydraulic conditions, and each one has a purpose, whether it is to dose the drip zone, clean the drip tubing, or back wash the disc filters.
- All three hydraulic conditions will be used at different times during the process of operating the hydraulic unit.

[← BACK](#)[HOME](#)[NEXT →](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

System Components — Hydraulic Unit

Chapter 4 B

Hydraulic Unit

page 9 out of 10

Three Hydraulic Conditions:

Different flows in particular paths are required to perform different hydraulic conditions.

1) Back-Washing Disc Filters

- Each filter in the hydraulic unit is back washed individually at the beginning of each dose cycle. The back washing cleans the filters. This takes 30 seconds to occur.
- This should be the most limiting condition, thus creating the greatest demand on the pump.

2) Routine Zone Dosing

- A drip zone is dosed during this hydraulic condition. Typically, each zone will be dosed four times a day.
- This should be the least limiting condition, thus creating the least amount of demand on the pump.

3) Drip Tubing Forward Field Flush

- This hydraulic condition cleans the drip tubing in the drip zones.
- The drip zone will typically be forward field flushed every 50 doses.
- The normal dose plus extra flow is pushed through the system during this hydraulic condition. At this time, the return line is also open, which allows debris to flow through the drip tubing. Then the effluent goes through piping in the hydraulic unit and back into the building sewer. This process will remove the debris from the drip tubing, and the debris will go through the primary and secondary treatment again.

Chapter 4 B

Hydraulic Unit

page 10 out of 10

Flow Rates:

These are the flow rates needed for certain hydraulic conditions. After the drip zones are laid out, the flows can be calculated. We will return to these flow rates later in the course.

A) Dosing Flow Rate

- This is the least limiting flow needed during routine zone dosing.
- The dosing flow rate for a particular zone is determined by the number of emitters in that zone.

B) Field Flush Flow Rate

- The flow required at distal ends of the laterals to achieve the proper scouring velocity (>2 ft./sec.).
- This flow rate is part of the flow needed for the drip tubing forward field flush hydraulic condition.
- This flow rate provides the velocity that will move solids.

$$\begin{array}{l} 1.6 \text{ gpm (Flow needed to achieve } >2 \text{ ft./sec. velocity.)} \\ \times \text{ number of laterals} \\ \hline = \text{ field flush flow rate} \end{array}$$

C) Total Drip Tubing Forward Field Flush Flow Rate

- The flow used during the drip tubing forward field flush hydraulic condition.

$$\begin{array}{l} \text{dosing flow rate (A)} \\ + \text{ field flush flow rate (B)} \\ \hline = \text{ total drip tubing forward field flush flow rate (C)} \end{array}$$

Calculating Total Linear Feet of Drip Tubing:

Soil Linear Load

Section 12.B. Drip Irrigation Zone 3

The soil linear load is found on the soil scientist's soil morphology report. (This report is in [the appendix](#).)

Maximum soil linear load = .34 gpd/linear feet of tubing

What does the .34 gal. per day/linear foot mean?

It means .34 gallons of effluent per foot of tubing can be discharged each day. This is the maximum amount of effluent the soil can absorb in a day to properly renovate the effluent.

Total Linear Feet of Drip Tubing—Smith Design

400 gal. per day

÷ soil linear load

= total drip tubing required in linear feet

[Back to the Table of Contents](#)

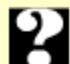

Drip Irrigation Training Course

System Components — Drip Zones

Chapter 4-C Minimum Site Length of the Drip Irrigation Zones page 14 out of 17

What does 43.5 feet in the Smith design mean?

There must be a minimum of 43.5 feet of site length for the drip irrigation zones.

Why is the 43.5 feet important? Why can't the site length be less than 43.5 feet?

The DEP alternate and experimental guidance states that the site length cannot be less than 43.5 feet for a system with a peak daily flow of 400 gpd. This is to keep the system long and narrow and placed along contours.

System Components — Drip Zone Components

Chapter 4 D

Component 2: Drip Emitters

page 5 out of 12

Section 12.B.Drip Irrigation Zone.4

- Pressure-compensating emitters are required in Pennsylvania. They provide even distribution of effluent on slopes and over sites with uneven run lengths.
- The pressure-compensating emitter will maintain a constant flow rate of .65 gph over a pressure range of 7 to 60 psi.
- During the manufacturing process, the drip emitters are placed 2 feet apart in the drip tubing.
- Drip irrigation is a timed-dose system. Since the discharge emitters deliver the same volume per minute, the zones can be different sizes. The timer can be set to deliver the correct volume dose of effluent to different zones.

Note: The American Septic Drip System has the only drip emitter that meets DEP's alternate and experimental guidance requirements at this time.

Chapter 4 D

Component 4: Supply and Return Lines

page 8 out of 12

- The supply line takes the effluent from the hydraulic unit to the supply manifold, which then takes the effluent to the lateral.
- The return line takes the effluent coming out from the lateral through the return manifold into the common return line. The common return line takes the effluent back to the building sewer.
- The supply and return lines can be placed on the same side of the zone or on opposite sides.

Chapter 4 D

Component 5: Supply and Return Manifold Connections

page 9 out of 12

The manifold connections are at the beginning and the end of each lateral. They take the effluent in and out of the lateral.

The diagram illustrates a two-zone drip irrigation system. It shows two zones, Zone 1 (green) and Zone 2 (orange), each with a series of laterals. A supply manifold on the left connects to supply lines for both zones. A return manifold on the right collects water from the laterals. An air-release valve followed by a check valve is located at the end of the return line. Labels include: Run, Zone 2, Zone 1, Lateral, Common return line, Supply manifold, Supply manifold connections, Supply line Zone 2, Supply line Zone 1, Air-release valve followed by a check valve, Return manifold, and Return manifold connections.

The photograph shows a close-up of the manifold connections in a field. A long white pipe (manifold pipe) runs horizontally. Short white pipes and fittings (manifold connections) connect the drip tubing to the manifold pipe. Black tubes (connectors) connect the drip tubing to the manifold connections.

Manifold Connections

The black tubes are connectors that connect the drip tubing to the manifold connection. The long white pipe is the manifold pipe, and the short white pipes and fittings are the manifold connections.

Chapter 4 E

Review of the Hydraulic Conditions

page 3 out of 11

You will learn how to determine if a dosing pump is sized properly in Chapter 5.

The dosing pump to the hydraulic unit must be sized for the hydraulic condition that creates the greatest demand on the pump.

Review of the Hydraulic Conditions

- 1) Back-washing disc filters
- 2) Routine zone dosing
- 3) Drip tubing forward field flush

To determine which hydraulic condition creates the greatest demand on the pump, you will need to calculate the total flow required for each drip zone during the drip tubing forward field flush hydraulic condition.

Chapter 5 A

Calculating Total Head Loss

page 3 out of 16

To calculate the total head loss to size the dosing pump, you will need to total the following head loss numbers.

- 1) Head Loss to the Hydraulic Unit
- 2) Friction Loss Through the Hydraulic Unit
- 3) Friction Loss Through the Zone Supply Lines
- 4) Flushing Requirements Through the Drip Tubes
- 5) Friction Loss Through the Common Return Line
- 6) Zone Static Head Loss

These numbers will all be calculated in this chapter using the Smith design as an example.

Make sure you have the design review worksheet printed out from [the appendix](#). You will be using pages 3 and 4 from the design review worksheet to help calculate the total head loss for the Smith design and then size the dosing pump.

Total Head Loss to Size the Dosing Pump — Smith Design

Chapter 5 A

1) Head Loss to the Hydraulic Unit

page 4 out of 16

Head Loss

Head loss is the amount of force behind the fluid that is lost due to elevation change and friction inside of the pipe. The head loss must be calculated to determine how much head the pump must begin with to withstand the head loss and end up with the correct amount of head at the end of the piping system.

Chapter 5 B

Review

page 14 out of 14

To calculate the total head loss to size the dosing pump, you will need to total the following head loss numbers.

- 1) Head Loss to the Hydraulic Unit = 9.2 feet**
- 2) Friction Loss Through the Hydraulic Unit = 6 feet**
- 3) Friction Loss Through the Zone Supply Lines**
 - Zone 1 = 5.5 feet**
 - Zone 2 = 5.8 feet**
- 4) Flushing Requirements Through the Drip Tubes
- 5) Friction Loss Through the Common Return Line
- 6) Zone Static Head Loss

Chapter 5 C

Calculating Total Head Loss

page 3 out of 19

In Sections A and B, you learned how to calculate the head loss to the hydraulic unit, the head loss through the hydraulic unit, and the friction loss through the zone supply lines. In Section C you will learn how to calculate the flushing requirements, the friction loss through the common return line, and the zone static head loss.

- 1) Head Loss to the Hydraulic Unit = 9.2 feet
- 2) Friction Loss Through the Hydraulic Unit = 6 feet
- 3) Friction Loss Through the Zone Supply Lines
 - Zone 1 = 5.5 feet
 - Zone 2 = 5.8 feet

4) FLUSHING REQUIREMENTS THROUGH THE DRIP TUBES

5) FRICTION LOSS THROUGH THE COMMON RETURN LINE

6) ZONE STATIC HEAD LOSS

ZONE 1 =

ZONE 2 =

These numbers will all be calculated in this chapter using the Smith design as an example.

Make sure you have the design review worksheet printed out from [the appendix](#). You will be using pages 3 and 4 from the design review worksheet to help calculate the total head loss for the Smith design and then size the dosing pump.

Chapter 5 C 4) Flushing Requirements Through the Drip Tubes page 4 out of 19

- During flushing through the drip tubes, a certain head is required to achieve the scouring velocity (2 ft./sec.) at the distal end of the longest drip irrigation lateral of each zone.
- The flushing value in feet comes from Table 3A. This table will provide the head loss in feet through the drip tubes. This table is found in [the appendix](#).
- To use Table 3A, take the maximum drip irrigation lateral length for a zone and read the number to the right in the head loss in feet column.

Drip Irrigation Training Course

Calculating the Dose — Smith Design

Chapter 6

Peak Flow Dose

page 22 out of 25

Calculating Peak Flow Dose

Summary

In the Smith design example, zones 1 and 2 at peak flow would each dose 30 gallons for 9.1 minutes 6.7 times a day.

The minutes the system doses the zones at the peak or average flow are always the same. The frequency of the dose is just more with the peak flow. The manufacturer recommends calculating each flow to make sure the minutes of run time is the same for both flows. If the minutes differ, the calculations should be reviewed again.

Note: The system will dose the average flow unless a peak flow occurs. The control panel will only activate the peak flow dose frequency if the peak-enabler float is activated. If the household is discharging its peak flow, the peak-enabler float tells the control panel that there is enough effluent in the tank to dose at the peak flow dose calculation.

[← BACK](#)[HOME](#)[NEXT →](#)

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Calculating the Dose — Smith Design

Chapter 6

Float Settings

page 23 out of 25

The Timer Controls the Dose

The floats in the dosing tank tell the control panel that enough effluent is in the tank to dose the system. When the control panel hits the correct time to dose and the floats have signaled to the control panel that enough effluent is present, the pump will turn on for the prescribed minutes and dose effluent to the zone.

Drip Irrigation Training Course

Calculating the Dose — Smith Design

Chapter 6

Placement of Floats

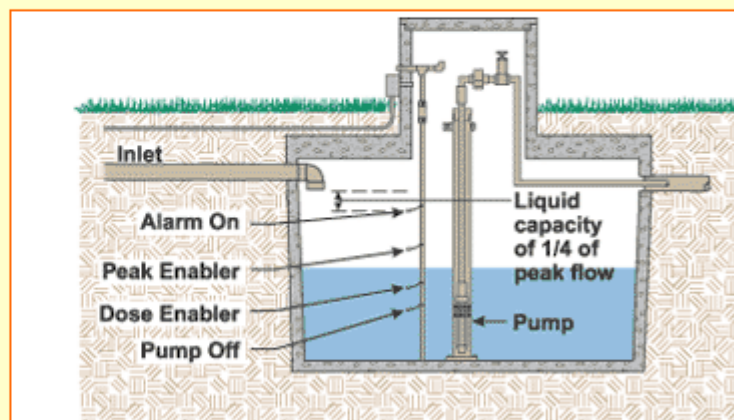

page 24 out of 25

- **Pump-off** float is placed above top of pump.
- **Dose-enabler** float is placed between pump-off float and peak-enabler float.

Note: American Manufacturing will set the two above floats.

- **Peak-enabler** float is placed halfway between the alarm-on and the dose-enabler float.

- **Alarm-on** float is between the bottom of the inlet and the peak-enabler float. The distance between the alarm-on float and the bottom of the tank inlet must provide enough liquid capacity to hold a minimum of one quarter of the peak flow. [In the Smith design, this would be at least 100 gallons (400 gallons \div 4 = 100).]

Note: The volume of water between the dose enabler- and alarm-on float must be a minimum of 1/2 to a full days design flow.

Drip Irrigation Training Course

Calculating the Dose — Smith Design

Chapter 6

Advantage of the Drip Irrigation System

page 25 out of 25

- One of the unique features of the drip irrigation system is that equal distribution is achieved with pressure-compensating emitters. This allows for different sized zones to be used in the same system.
- The pressure-compensating emitters discharge rate per minute is the same between 7 and 70 psi. This causes the drip emitters to discharge the same amount of effluent per linear foot. This is how equal distribution is achieved. Therefore, if all zones have the same run time and the same number of doses each day, then they will receive the same amount of effluent per linear foot. This is why the uniformity of soil loading is provided regardless of pump pressure, distance to the field, slope, or topography.

Construction

page 20 out of 24

SEOs should know the particulars of how and when a drip irrigation system should be constructed and installed.

Section 12.C.1

- 1) No wet weather installation. Soil moisture content must be at or below field capacity for drip line installation.

Soil moisture field test:

- A) Squeeze a handful of soil in one hand.
- B) Open your hand.
- C) Bounce the sample once lightly in your hand or tap the soil lightly with your finger.

If the sample of soil crumbles or breaks up immediately when bounced or tapped, the soil moisture should be acceptable, and construction can occur. If the sample sticks together, the soil moisture is unacceptable, and construction should be postponed.

[← BACK](#)[HOME](#)[NEXT →](#)

Drip Irrigation Training Course

Installation and Construction

Chapter 7

Construction

page 21 out of 24

- 2) No activity must occur on the drip zones. No parking of equipment or storage of materials is permitted over the drip zones.
- 3) The system should be installed as permit requires.
- 4) All PVC pipe and fittings must be PVC Schedule-40 type-1 rated for pressure applications. All glued joints must be cleaned and primed with purple (dyed) PVC primer prior to being glued.
- 5) All pipe, flexible PVC, and/or dripper tubing should be cut with pipe cutters. If sawing is done, all shavings from the sawing must be cleaned out of the pipe.
- 6) All PVC pipe, flexible PVC, and/or dripper tubing in the work area must have the ends covered with duct tape to prevent construction debris from entering the pipe. Prior to gluing, all glue joints must be inspected for and cleared of construction debris.

Return trench with drip lines taped to prevent debris from getting into the tubing. These tubes will be connected to the return manifold or a drip loop connector.

Chapter 7

Construction

page 22 out of 24

- 7) Prior to starting up the drip system, the air-release valves must be removed, and each zone in the system must be flushed as follows:
 - a) Attach an appropriate length of flexible PVC pipe with a male fitting to the air-release connection to direct the flushing away from the construction area.
 - b) Flush the zone with a volume of clean water equal to 1.5 times the volume of the pipes from the hydraulic unit to the air-release valve.
 - c) Repeat this procedure for each zone.
- 8) If existing treatment tank(s) to be used, they must be pumped out by a commercial septic tank pumper. After the tank(s) are emptied, they must be rinsed, pumped, and refilled with clean water. Debris in treatment tank(s) must be kept to a minimum since it could clog the disc filters during start up.

Instructions: Choosing from the blue area, click on each of the final operational inspections in the correct sequence from one to five.

1

Check the pump and control panel.

2

Do an extended check of the zone dose rates.

3

Check the field conditions.

4

Check the control lights and manual switch position.

5

Verify pump tank liquid.

Operation and Maintenance

Chapter 9 Home Owner and Factory Representative Meeting page 3 out of 6

The following two operation and maintenance conditions must be attached to the permit issued by the local agency:

Section 12.D.1

- 1) The manufacturer's representative must meet with the property owner within one month of occupancy of the dwelling and with the local agency's SEO upon request. At this meeting, the manufacturer's representative must explain the operation and maintenance of the system and provide written instructions to the property owner that include:
 - a) Instruction on the operation and maintenance of the system.
 - b) The location of all parts of the system.
 - c) A caution notice regarding disturbances of the drip zones that may cause system damages (i.e., excavation of trees, fencing, etc.)
 - d) An explanation of the automatic alarm system.
 - e) A statement requiring that the manufacturer's representative be contacted if the alarm system is activated.

Section 12.D

The only drip irrigation system that has met the requirements for the alternate system listing to date is

Perc-Rite® System, manufactured by the American Manufacturing Company, Incorporated (5517 Wellington Road, Gainesville, VA 20155
americanonsite.com - 800-345-3132.)

All proposals for the application of drip irrigation systems that fall outside the standards established by the alternate system listing must be proposed and reviewed as experimental systems under the provisions of Chapter 73.71.

- Drip irrigation is an alternate technology approved by the Department of Environmental Protection.
- Drip irrigation achieves equal distribution through the pressure-compensating drip emitters.
- Drip irrigation can use the available space on a lot, because the zones can be different sizes.
- A drip irrigation system is buried in the ground. It could be in the front yard, but no one would know it was there.

Top Feed Manifold

Chapter 11 Why Should a Top Feed Manifold Be Used page 3 out of 10

American Manufacturing is recommending that sites with a slope of greater than five percent to use top feed manifolds.

If the site has a slope of more than five percent, the drip irrigation system should be designed with a top feed supply manifold and a top feed return manifold. If the site has a slope of five percent or less, the **supply** manifold connection and **return** manifold connection as described in the course should be used.

[Back to the Table of Contents](#)

Drip Irrigation Training Course

Top Feed Manifold

Chapter 11 Why Should a Top Feed Manifold Be Used page 4 out of 10

Why should a top feed manifold system be used on steeper slopes?

The top feed manifold system helps prevent drain down of upper laterals in the zone to lower laterals in the zone. This may help prevent overloading of the lower laterals within a zone after the pump shuts off. By using these "top feed" manifolds the only thing that changes in the entire system is the way in which the drip lines are fed from the main supply line, and back into the common return line.

Drip Irrigation Training Course

Top Feed Manifold

Chapter 11

Design of Top Feed Manifold

page 8 out of 10

2) Valves That Should Go With the Manifold System.

Return Top Feed Manifold

Each top feed return manifold needs an air release valve and a **check valve**.

The **air release valve** provides ready venting of the distribution system, enhancing drainage of tubing and the top feed manifold. It also provides freeze protection.

The **check valve** prevents effluent from entering the zone when another zone is being dosed.

Drip Irrigation Training Course

Top Feed Manifold

Chapter 11

Design of Top Feed Manifold

page 9 out of 10

3) How to Calculate for the Head Loss of the Manifold System.

When determining the head loss for the top feed manifold add 50 feet of pipe equivalent length for the supply and 50 feet of pipe equivalent length for the return manifold. The 50 feet on both the supply and return manifolds is more than enough to cover the head loss through the top feed manifold.

When reviewing the head loss calculations make sure the designer added the 50 feet of pipe equivalent length for both the supply and return manifold, if the top feed manifold was used.

Soil Morphological Report

August 1, 2001

Tom and Sue Smith
1234 Lake Drive
Harrisburg, PA 17011

Dear Mr. And Mrs Smith:

On July 20, 2001, the soil conditions at your residential property were evaluated with regard to morphological characteristics and the corresponding suitability for a drip irrigation installation. The investigation was conducted in the presence of the township Sewage Enforcement Officer (SEO), who is responsible for the design review and permit approval of this alternate system, in accordance with the Department of Environmental Protection, January 2000 *Alternate and Experimental Systems Guidance* document.

Several backhoe excavations were examined in order to establish depth to seasonal water table, rock limiting condition depth, drainage classification, and the morphological indicators used to design the drip irrigation system. In addition, soil borings were hand augered throughout the proposed absorption area to confirm the soil conditions described in the individual soil test probes. The following summarizes the actual soil conditions present and provides specific criteria, which will be used in the preparation of an individual design for this alternative technology.

The soil conditions at your proposed residential absorption area were characterized by a professional member of the PA Association of Professional Soil Scientists (PAPSS), who is also recognized as a Qualified Soil Scientist as defined in Chapter 73, Section 73.1. The soils were characteristic of the Laidig soil series, which confirms the mapping provided by the NRCS Dauphin County Soil Survey. The soils within the proposed absorption area are (e.g., deep and well drained), with a maximum slope of 11 percent. Depth to a seasonal water table was noted at 42 inches, and the most shallow indication of a rock limiting condition was 62+ inches. Based upon these general observations, a drip irrigation system may be further considered.

The accompanying soil profile description(s) provides additional morphological detail, which may be used to prepare a design for a drip irrigation system for your residential lot. Based upon the morphology of the soil, a maximum soil linear load rate of .33 gallons per linear foot per day may be used. The horizontal linear load must not exceed 4.6 gallons per day as calculated on the average daily flow of your proposed system. Drip line tubing shall be installed to a depth of 6 inches, with a horizontal separation of 1.5 feet. Based upon this design criteria, a site plan for the individual drip irrigation zones may be developed.

The accompanying design plan displays the individual soil test probe locations and the proposed absorption area necessary for this alternative sewage treatment and disposal technology. This approved area must remain undisturbed prior to actual design stake-out, permit issuance, and installation. A copy of this report has been submitted to the SEO for his review and approval and should be included in the subsequent design drawings to be submitted with your septic permit application.

If I can provide you with any additional information at this time with regard to the existing soil conditions encountered or the corresponding drip irrigation design criteria, please feel free to contact me. Thank you for the opportunity to provide these services on your behalf.

Respectfully submitted,

Rick Smith

Rick Smith
Qualified soil scientist

Notes:

- 1 Values are for 100 feet of Schedule-40 pressure-rated pipe.
- 2 Actual I.D. of pipe: 1.049, 1.61, 2.067, 3.068, 4.026, 6.065
- 3 Formula for friction loss is: $H_f = \frac{10.46 (Q / C)^{1.852}}{D^{4.87}} \times 100$

Q = flow (gpm)
 C = coefficient of roughness (150)
 D = actual I.D. of pipe (inches)

NOTE #1: Proposed 1,500-gallon two-compartment septic tank. Provide a 4" maximum inspection port over first compartment inlet baffle. Solids retainer unit required on final compartment outlet baffle.

NOTE #2: Proposed 500-gallon free access sand filter pump tank.

NOTE #3: Proposed two (2) 40-square-foot free-access sand filter tanks to be dosed simultaneously.

NOTE #4: Proposed 1,000-gallon drip irrigation dose tank with pump.

NOTE #5: Proposed central hydraulic unit and control panel (simplex system with 2 zones and 2 disc filters from American Manufacturing Company)

DESIGN PLAN

Scope:

Household sewage will flow by gravity through a treatment unit, typically a septic tank, to the sand filter feed tank. From the sand filter feed tank, the effluent is pumped to the sand filter where, after treatment, it flows by gravity to the drip dose tank for disposal. The central unit will dispose of the effluent by alternately dosing multiple zones in the soil absorption area. The central unit comprises both the hydraulic and control units.

General Notes - Drip Disposal

1. All installation and construction techniques shall conform to county codes and State Board of Health "Sewage Handling and Disposal Regulations" pertaining to on-site sewage systems and the permit for this site.
2. The installation of this system shall be in accordance with specifications and procedures as supplied by the manufacturer of the equipment.
3. All PVC pipe and fittings shall be PVC Sch-40 Type 1 rated for pressure applications. All glued joints shall be cleaned and primed with purple (dyed) PVC primer prior to being glued.
4. All cutting of PVC pipe, flexible PVC and dripper tubing shall be accomplished with pipe cutters approved by manufacturer. No sawing of PVC, flexible PVC, or dripper tubing allowed.
5. All PVC pipe, flexible PVC, and dripper tubing in the work area shall have the ends covered with duct tape to prevent construction debris from entering the pipe. Prior to gluing, all joints shall be inspected for and cleaned of any construction debris.
6. No wet weather installation is permitted.
7. No activity on drainfield area other than minimum required to install system. Do not park equipment, drive large equipment over, or store materials on drainfield site.
8. Horizontal spacing between dripper lines and the installation depth shall be as specified.
9. Prior to start-up of the drip disposal system, the air-release valves shall be removed and each zone in the system shall be flushed as follows: a) Using an appropriate length of flexible PVC pipe with a male fitting attached to the air-release connection to direct the flushing water away from the construction area; b) Flush the zone with a volume of water (clean water to be provided by contractor) equal to 1.5 times the volume of the pipes from the central unit to the air-release valve; c) Repeat this procedure for each zone (the flushing of the system is accomplished by manual override of the control panel by the manufacturer or engineer).
10. If existing septic tanks are to be used, they shall be pumped out by a commercial septic tank cleaner. After the tank is emptied, it shall be rinsed, pumped, and refilled with clean water. Debris in septic tank must be kept to a minimum as it could clog the disc filters during start-up. If used septic tanks must be watertight.
11. If trees are to be removed from site, cut stumps flush with ground. Remove by hand.
12. Gravel base under central control unit is to be drained via 2" PVC pipe, screened at inlet and outlet, discharge to be at grade downslope (to ensure drainage of surface water from unit).
13. The contractor shall be certified to install this type of system by the manufacturer and shall hold a preconstruction meeting with the individuals responsible for soil evaluation, permitting, and inspections prior to site work beginning to ensure protection of the site conditions and to ensure the system is installed according to design.
14. If site conditions are determined to require the installation of the system to deviate from these plans, all site work shall stop immediately and the designer shall be notified. Any ongoing work shall be at the sole responsibility of the contractor.
15. Operation and maintenance manual to be provided at job completion.

* Drip lines are 6 inches below grade, with emitters every 2 feet.

* Drip lines are 1.5 feet on center.

* Drip lines follow contours.

* PVC manifold perpendicular to contours.

* See attached hydraulic profile sheet for all elevations.

* Static head; hydraulic unit pump dose enabler float to hydraulic unit base; 8 feet max.

* Static head; hydraulic unit base to highest drip emitter; 40 feet.
